

41~42번

Flashback to 50,000 years ago on the Serengeti, and you are dragging an antelope back to the village. Let us just say it has cost you, metabolically speaking, 2,000 calories to stalk, chase and bring down the antelope. When you get back to the village, you would clearly have to consume at least 2,000 calories to recover your expenditure. But there is no guarantee that you would successfully get an antelope the next time out, so if you ONLY ate to your metabolic need, you wouldn't survive very long. That is when the hedonic part of the brain, which governs the feeling of reward kicks in, driving you to eat more. But how do you get past the mechanical difficulty of a stomach packed full with 2,000 calories of meat? Your brain becomes more picky, it begins to desire foods that are more calorically dense and more calorically available, which are going to be foods high in free sugars and fat. What foods are high in free sugars and fat? Desserts. Your dessert stomach is an evolutionary leftover from your days in the Serengeti, to make sure that even when full, you were still desiring the right types of foods to ensure you were able to maximize your caloric intake at every meal, because there was never a guarantee of when the next meal would arrive. It kept us alive in regular feast-famine cycles, but has become toxic for many of us in the feast-feast environment of today.
